

Long-Term Outcomes of Glenohumeral Arthrodesis

Retrospective review of 29 shoulders
that had undergone primary glenohumeral arthrodesis

Screw

Plate and screw

Average age
42 (17 – 69)

Average follow-up

Indications

- Chronic infection
- Neurologic injuries
- Recurrent dislocations
- Proximal humeral or shoulder girdle tumors
- Rotator cuff arthropathy and pseudoparalysis

High rate of complications

41% had complications
24% were nonunion

Daily limitations

87% reported limitations

Reasonable pain relief

Rate of moderate/severe pain
dropped from 93% to 34%

Better function with an
arthrodesis position $\geq 25^\circ$

Worse outcomes associated
with brachial plexopathy

Glenohumeral arthrodesis, used in cases with high levels of preoperative limitation, has a high rate of complications and functional limitations but can provide pain relief and shoulder stability.

Long-Term Outcomes of Glenohumeral Arthrodesis
