

**Supplementary Fig. 1. Schematic of the setup to record laser-evoked ERPs in rats.**

Infrared neodymium yttrium aluminum perovskite (Nd:YAP) laser pulses activate selectively nociceptive terminals in the superficial skin layers. Laser pulses are delivered through an optic fibre to the freely moving rat. EEG signals are transmitted through flexible wires to the EEG amplifier and recording system. EEG data are recorded from 14 electrodes placed according to stereotaxic coordinates. The coordinates of 12 active electrodes are as follows (positions are expressed in respect to the Bregma, in mm; positive X and Y axis values indicate right and anterior locations, respectively). FL1: X=-1.5, Y=4.5; FR1: X=1.5, Y=4.5; FL2: X=-1.5, Y=1.5; FR2: X=1.5, Y=1.5; LFL: X=-4.5, Y=0; RFR: X=4.5, Y=0; PL1: X=-1.5, Y=-1.5; PR1: X=1.5, Y=-1.5; LPL: X=-4.5, Y=-3; RPR: X=4.5, Y=-3; PL2: X=-1.5, Y=-4.5; PR2: X=1.5, Y=-4.5. Reference (REF) and ground (GRD) electrodes are respectively placed at 2 mm and 4 mm caudally to the Lambda, on the midline.

**Supplementary Fig. 2. Statistical assessment of the significance of the laser-evoked brain responses (Experiment 2).**

Without ongoing white noise, both early "A $\delta$ -ERP" and late "C-ERP" responses were significantly different from the pre-stimulus variability (top panels). With ongoing white noise, only the late "C-ERP" responses were significantly different from the pre-stimulus variability, whereas the early "A $\delta$ -ERP" responses were not (bottom panels). The red lines indicate the  $p=0.05$  threshold (corresponding to 1.96 times the averaged variability – estimated as SD – of the pre-stimulus fluctuations across subjects).

**Supplementary Table 1.** Latency and amplitude of ERPs elicited by laser stimulation at different sites (tail base and tip) and energies (E1-E5) (Experiment 1).
