

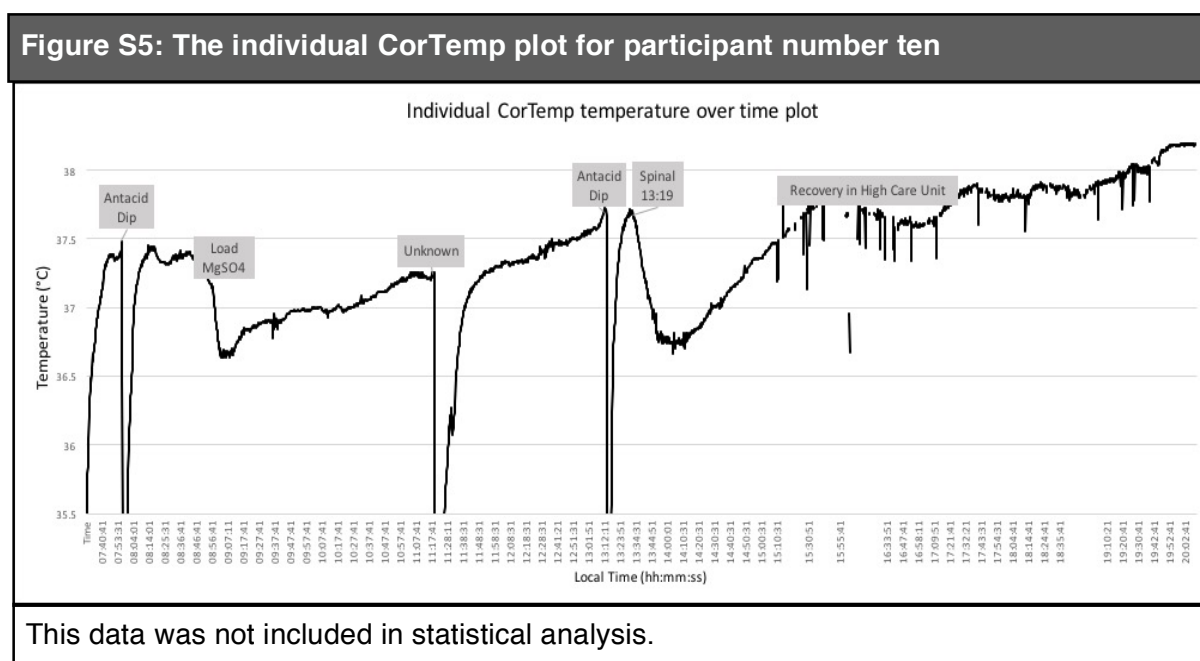

Figure S5: The individual CorTemp data plot for participant number ten. The figure reports the data of participant ten who was excluded from statistical analysis.

On arrival in the operating theatre participant number ten had Sodium Citrate antacid. This event coincided with the first temperature dip labelled “Antacid Dip” in Figure S5. When the non-invasive blood pressure monitor was connected the participant was significantly hypertensive. Review of her chart from the previous night revealed high blood pressure readings overnight. The decision was made to postpone the case while the participant is investigated for gestational proteinuric hypertension. The data plot reveals a second temperature dip around 08:45 am associated with intravenous MgSO₄ loading. A deep temperature dip around 11:15 am resembles ingestion of a cool drink. After 13:00 the participant is taken back to the operating theatre where she ingests a second dose of Sodium Citrate antacid (second “Antacid Dip” labelled in the data plot). Spinal anesthetic injection was given at 13:19. The participant was moved to the obstetric high care unit shortly after leaving the operating theatre table. A large amount of artifact is seen in her data during her recovery in the high care unit. It is unclear what caused the excessive artifactual data during this period.
